Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Data structure:** A data structure specifies the way of organizing and storing **in-memory** data that enables **efficient access** and **modification** of the data.
 - **Linear Data Structures**
 - **Non-linear Data Structures**
- Most data structure has a container for the data and typical operations that its needs to perform
- For applications relating to data management, the key operations are:
 - Create
 - Insert
 - Delete
 - Find / Search
 - Close
- Efficiency is measured in terms of time and space taken for these operations

Module 38

Build a BST

Search a Key

Comparison

Module Summary

- From the study of **Linear data structures** in the last module, we can make the following summary observations:
 - All of them have the space complexity $O(n)$, which optimal. However, the actual used space may be lower in array while linked list has an overhead of 100% (double)
 - All of them have complexities that are identical for Worst as well as Average case
 - All of them offer satisfactory complexity for some operations while being unsatisfactory on the others

	Array		Linked List	
	Unordered	Ordered	Unordered	Ordered
Access	$O(1)$	$O(1)$	$O(n)$	$O(n)$
Insert	$O(n)$	$O(n)$	$O(1)$	$O(1)$
Delete	$O(n)$	$O(n)$	$O(1)$	$O(1)$
Search	$O(n)$	$O(\lg n)$	$O(n)$	$O(n)$

- Non-Linear data structures** can be used to trade-off between extremes and achieve a balanced good performance for all

Non-linear Data Structures (2)

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Nonlinear data structures** are those data structures in which data items are not arranged in a sequence and each element may have multiple paths to connect to other elements.
- Unlike linear data structures, in which each element is directly connected with utmost two neighbouring elements (previous and next elements), non-linear data structures may be connected with more than two elements.
- The elements don't have a single path to connect to the other elements but have multiple paths. Traversing through the elements is not possible in one run as the data is non-linearly arranged.
- Common Non-Linear Data Structures include:
 - **Graph**: Undirected or Directed, Unweighted or Weighted, and variants
 - **Tree**: Rooted or Unrooted, Binary or n-ary, Balanced or Unbalanced, and variants
 - **Hash Table**: Array with lists (coalesced chains) and one or more hash functions
 - **Skip List**: Multi-layered interconnected linked lists
 - and so on

Non-linear Data Structures (3): Graph

Module 38

Partha Pratim
Das

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Graphs:** Graph G is a collection of vertices V (store the elements) and connecting edges (links) E between vertices: $G = \langle V, E \rangle$ where $E \subseteq V \times V$

- A graph may be:
 - Undirected or Directed
 - Unweighted or Weighted
 - Cyclic or Acyclic
 - Disconnected or Connected
 - and so on
- Examples of a graph include:
 - ER Diagram
 - Network: Electrical, Water
 - Friendships in Facebook
 - Knowledge Graph

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Tree**: Is a connected acyclic graph representing hierarchical relationship

- A tree may be:
 - Rooted or Unrooted
 - Binary or n-ary
 - Balanced or Unbalanced
 - Disconnected (forest) or Connected
 - and so on
- Examples of a tree include:
 - Composite Attributes
 - Family Genealogy
 - Search Trees
 - and so on

Non-linear Data Structures (5): Tree

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Root:** The node at the top of the tree is called root. There is only one root per tree and one path from the root node to any node. **A** is the root node.
- **Parent:** The node which is a predecessor of any node is called parent node. In the given tree, **B** is the parent of **E**. Every node, except the Root, has a unique parent
- **Child:** A node which is the descendant of a node: **D**, **E** and **F** are the child nodes of **B**
- **Leaf:** A node which does not have any child node: **I**, **J** and **K** are leaf nodes

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Internal Nodes:** The node which has at least one child is called internal Node
- **Subtree:** Subtree represents the tree rooted at that node
- **Path:** Path refers to the sequence of nodes along the edges of a tree
- **Siblings:** Nodes having the same parents: **D**, **E** and **F** are the siblings.
- **Arity:** Number of children of a node. **B** has arity 3, **E** has arity 2, **G** has arity 1, and **D** has arity 0 (**Leaf**)

Maximum arity of a node is defined as the arity of the tree.

Non-linear Data Structures (7): Tree

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Levels:** The root node is said to be at Level 0 and the children of the root node are at Level 1 and the children of the nodes which are at Level 1 will be at Level 2 and so on.

Level is the length of the path (number of links) or distance of a node from the root node. So, level of **A** is 0, level of **C** is 1, level of **G** is 2, and level of **J** is 3.

- **Height:** Maximum level in a tree
- **Binary Tree:** is a tree, where each node can have at most 2 children. It has arity 2.

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Fact 1:** A tree with n nodes has $n - 1$ edges
- **Fact 2:** The maximum number of nodes at level l of a binary tree is 2^l .
- **Fact 3:** If h is the height of a binary tree of n nodes, then:
 - $h + 1 \leq n \leq 2^{h+1} - 1$
 - $\lceil \lg(n + 1) \rceil - 1 \leq h \leq n - 1$
 - $O(\lg n) \leq h \leq O(n)$
 - For a k -ary tree, $O(\lg_k n) \leq h \leq O(n)$

Non-linear Data Structures (9): Hash Table (Module 44)

Module 38

DasObjectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Hash Table (Hash Map)**: implements an associative array abstract data type, a structure that can map keys to values by using a hash function to compute an index (hash code), into an array of buckets or slots, from which the desired value can be found

- A hash table may be using:
 - Static or Dynamic Schemes
 - Open Addressing
 - 2-Choice Hashing
 - and so on
- Examples of a hash table include:
 - Associative arrays
 - Database indexing
 - Caches
 - and so on

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- During the study of linear data structure, we observed that
 - Binary search is efficient in search of a key: $O(\lg n)$. However,
 - ▷ it needs to be performed on a sorted array, and
 - ▷ the array makes insertion and deletion expensive at $O(n)$
 - The linked list, on the other hand is efficient in insertion and deletion at $O(1)$, while it makes the search expensive at $O(n)$.
 - ▷ *$O(1)$ insert / delete is possible because we just need to manipulate pointers and not physically move data*
- Using the non-linearity, specifically (binary) trees, we can combine the benefits of both
- Note that once an array is sorted, we know the order in which its elements may be checked (for any key) during a search
- As the binary search splits the array, we can conceptually consider the *Middle Element* to be the *Root* of a tree and the *left (right) sub-array* to be its *left (right) sub-tree*
- Progressing recursively, we have a **Binary Search Tree**

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- **Binary Search Tree (BST):** Is a tree in which all the nodes hold the following:
 - The value of each node in the left sub-tree is less than the value of its root
 - The value of each node in the right sub-tree is greater than the value of its root

- **Structure of BST node:** Each node consists of an element (**X**), and a link to the left child or the left subtree (**LC**), and a link to the right child or the right subtree (**RC**)

Binary Search Tree (2)

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

```
search(root, key)
```

1. Compare the key with the element at root.
 - 1.1. If the key is equal to root's element then
 - 1.1.1 Element found and return
 - 1.2. else if the key is lesser than the root's element
 - 1.2.1 search(root.lc) #search on the left subtree
 - 1.3 else: #if the key is greater than the root's element
 - 1.3.1 search(root.rc) #search on the right subtree

Module 38

Partha Pratim
Das

Objectives &
Outline

Data Structure

Non-linear Data
Structures

Graph

Tree

Hash Table

Binary Search
Tree

Build a BST

Search a Key

Comparison

Module Summary

- Searching a key in a BST is $O(h)$, where h is the height of the key
- **Worst Case**
 - The BST is a skewed binary search tree (all the nodes except the leaf would have only one child)
 - This can happen if keys are inserted in sorted order
 - Height (h) of the BST having n elements becomes $n - 1$
 - Time complexity of search in BST becomes $O(n)$
- **Best Case**
 - The BST is a balanced binary search tree
 - This is possible if
 - ▷ If keys are inserted in purely randomized order, Or
 - ▷ If the tree is explicitly balanced after every insertion
 - Height (h) of the binary search tree becomes $\lg n$
 - Time complexity of search in BST becomes $O(\lg n)$
